## Homework Set 13: Driven Harmonic Motion Solution

## Problem From TM5.

1) 3-24 Altered For $\beta=0.2 \mathrm{~s}^{-1}$, Mathematic plots like those shown in Figure 3-15 for a sinusoidal driven, damped oscillator where $x_{p}(t), x_{c}(t)$, and the sum $x(t)$ are displayed on the back of this sheet. To produce them, I let $k=1 \mathrm{~kg} / \mathrm{s}^{2}, \mathrm{~m}=1 \mathrm{~kg}, A=-1 \mathrm{~m}$, the phase angle $\delta=0$, and plotted values of $\omega_{0} / \omega_{s}$ of $1 / 9$, $1 / 3,1.1,3$ and 6 . For the $x_{p}(t)$ solution (Eqn. 3.60). I let $F_{0} / \mathrm{m}=1 \mathrm{~m} / \mathrm{s}^{2}$, but calculatde $\delta$. For the last plot, in the $x_{p}(t)$ solution (Eqn. 3.60), I let $F_{0} / \mathrm{m}=20 \mathrm{~m} / \mathrm{s}^{2}$. For $\omega_{0} / \omega_{s}=6$, let $F_{0}=20 \mathrm{~m} / \mathrm{s}^{2}$ for $x_{p}(t)$ and produce the plot again.

What do you observe about the relative amplitudes of the two solutions as $\omega_{D}$ increases? Why does this occur?

The amplitude of the steady-state term can be seen to increase as $\omega_{\mathrm{D}}$ approaches the value of $\omega_{\mathrm{s}}$. then decrease as $\omega_{0}$ gets much larger than the value of $\omega_{s}$.

As seen in the $\omega_{D} / \omega_{s}=1 / 9$ and $1 / 3$, the sum is dominated by the transient with a large amplitude, but only in the first norind

$$
\omega_{D}=(1 / 9) \omega_{S}
$$

$$
\omega_{D}=(1 / 3) \omega_{S}
$$

Transient Steady State Sum

The dependence of the steady-state amplitude on the frequencies, in particular, the difference in the frequencies squared in the denominator, means its amplitude is maximized when the difference is the smallest. This is shown by the $\omega_{D} / \omega_{s}=1.1$ plot:

$$
H=\frac{F_{0} / m}{\sqrt{\left.\left(\omega_{N}^{2}-\omega_{D}^{2}\right)^{2}\right)}+\underbrace{}_{\begin{array}{c}
\text { Frequency } \\
\text { difference. }
\end{array} \begin{array}{l}
4 \beta^{2} \beta^{2} \omega_{D}^{2} \\
\text { this term } \\
\text { constant } \\
\text { and small. }
\end{array}}}
$$

Once $\omega_{0}$ is larger than $\omega_{s}$, the steady-state amplitude becomes increasingly small due to both terms in the denominator becoming large. In terms of warping, when $\omega_{\mathrm{D}}$ is smaller than $\omega_{s}$, the transient warps the steady state, but only for the first period. When they're nearly equal, the transient has the least effect. When $\omega_{s}>\omega_{D}$, the steady state warps the transient, but damps out after 3 periods as shown in the last two plots.

The plots show driven, under dampled harmonic oscillations for

$$
x(t)=A e^{-\beta t} \cos \left(\omega_{S} t\right)+\frac{F_{0} / m}{\sqrt{\left(\omega_{N}^{2}-\omega_{D}^{2}\right)^{2}+4 \beta^{2} \omega_{D}^{2}}} \cos \left(\omega_{D} t-\delta\right), \text { where } \delta=\tan ^{-1}\left(\frac{2 \beta \omega_{D}}{\omega_{N}^{2}-\omega_{D}^{2}}\right)
$$

with $F_{0} / m=k=1, \delta_{\text {transient }}=0, A=-1$, and $\beta=0.2 \mathrm{~s}^{-1}$ (giving $\omega_{N}=1 \mathrm{~s}^{-1}$ and $\omega_{s}=0.9798 \mathrm{~s}^{-1}$ ) and $\omega_{D}$ as multiples of $\omega_{N}$ as given on each plot.

$\omega_{D}=1.1 \omega_{S}$
