

## Lab Summary Spring 2026

### 1. Atlas Charts

Found the Atlas Charts for the Big & Little Dippers using the guide map and read them to learn about the stars in those asterisms and other objects in those areas of the sky.

### 2. Star Distances and Magnitudes

Used Appendix 2 to look up information about stars in the Summer Triangle and ranked them in order of distance, apparent magnitude ( $V$ ) and absolute magnitude ( $M_V$ ). Brighter objects have lower magnitudes ... Vega  $V_{\text{Vega}} = 0.03$  is brighter in the sky than Deneb  $V_{\text{Deneb}} = 1.25$ , but Deneb is intrinsically brighter than Vega:  $M_{V,\text{Deneb}} = -7.5$   $M_{V,\text{Vega}} = 0.6$ .

### 3. Celestial Coordinates

Identified stars on celestial globes using their coordinates and identified coordinates on the atlas chart sky maps.

Right Ascension (Celestial Longitude),  $0^h$  to  $23^h59^m59^s$  eastward from  $\gamma$

Declination (Celestial Latitude),  $0^\circ$  to  $\pm 90^\circ$  northward & southward from Celestial Equator

### 4. Changes in Latitude

Wrote down the altitudes of the celestial pole and celestial equator for various latitudes then identified them on horizon diagrams.  $\lambda$  = latitude of the observer.

**ALTITUDE OF CELESTIAL POLE = LATITUDE OF THE OBSERVER!**

### 5. Star Transit Times

We looked up the transit times for a variety of stars using p. 13 in the *Field Guide* in both standard (EST) and daylight saving time (EDT). Vega's transit times through the summer showed that stars transit 4 minutes earlier every night.

## 6. Rising, Setting and Time in the Sky

Looked up star names in Appendix 2 using their right ascension. From their declinations, calculated their rising and setting azimuths, maximum altitudes and times above the horizon.

For  $\lambda$  = latitude of the observer and  $\delta$  = declination of the star, we determined the azimuths of rising and setting, the altitude of the star at transit (the maximum), and the hours the star will be above the horizon using the following equations:

$$A_{\text{rise}} = \cos^{-1} \left( \frac{\sin \delta}{\cos \lambda} \right) \text{ degrees} \quad A_{\text{set}} = 360 - A_{\text{rise}} \text{ degrees}$$

$$A_{\text{max}} = (90 - \lambda) + \delta \text{ degrees} \quad \Delta t = \frac{2}{15} \cos^{-1} (-\tan \lambda \tan \delta) \text{ hours}$$

## 7. Time Zones

Wrote down the longitudes of the time zone centers in the western hemisphere, converted UT to EDT and EST. For cities at different longitudes, calculated the time of solar noon given the longitude of each city's time zone center.

Earth turns  $15^\circ/\text{hour}$ ,  $1^\circ$  in 4 minutes, and 15 arcminutes in one minute

$\Rightarrow$  an observer east of the TZ center sees events  $(\text{degrees}) \times \left( \frac{4 \text{ minutes}}{1 \text{ degree}} \right)$  early.

$\Rightarrow$  an observer west of the TZ center sees events  $(\text{degrees}) \times \left( \frac{4 \text{ minutes}}{1 \text{ degree}} \right)$  late.

## 8. Celestial Navigation

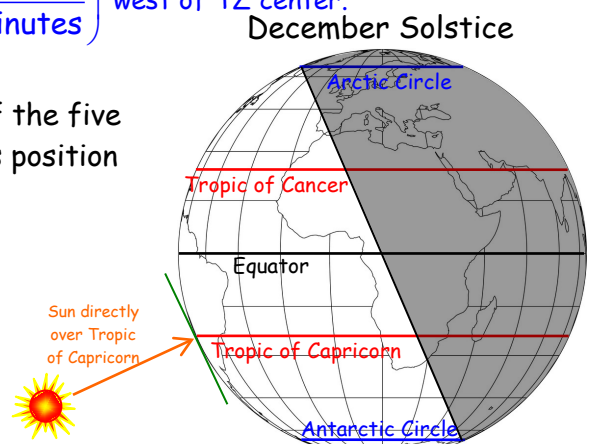

We determined an observer's latitude from the altitude of Polaris and longitude from the difference between the observed and expected transit times of Procyon on a particular day.

$\Rightarrow$  an observer who sees events early is  $(\text{minutes}) \times \left( \frac{1 \text{ degree}}{4 \text{ minutes}} \right)$  east of TZ center.

$\Rightarrow$  an observer who sees events late is  $(\text{minutes}) \times \left( \frac{1 \text{ degree}}{4 \text{ minutes}} \right)$  west of TZ center.

## 9. Named Latitudes

We determined wrote the geographic significance of the five named latitudes and shaded the Earth to show the Sun's position on the solstices and equinoxes.

## 10. The Ecliptic

We looked up the celestial position of the Sun on Sept. 10 in Leo. Used the Atlas Charts to determine information about the Solstices and Equinoxes.

The Ecliptic is the apparent annual path of the Sun across the sky and Earth's orbital plane.

**THE TABLE YOU FILLED OUT WILL BE ON THE EXAM VERBATIM! KNOW IT!**

## 11. The Day Through the Seasons

Using the Analemma to find solar declinations, we found the azimuths of rising and setting, the maximum altitudes and hours above the horizon for various cities. We also used the Analemma to determine the clock times of solar noon for various dates.

For observer at different latitudes ( $\lambda$ ) and different declination of the Sun ( $\delta$ ), we determined the azimuths of rising and setting, the altitude of the star at transit (the maximum), and the hours of daylight using the same equations as in lab exercise 6.

## 12. Astronomy and Astrology

Used Starry Night to look at the sky at the moments of our births from the places of our births. Compared the astronomical constellations the Sun, moon and planets were in to the astrological "houses" they were in according to our natal charts. Most of the constellations were different showing that astrology is not a scientific representation of the sky.

## 13. Planets in the Sky

Used Appendix 11 to look up planetary longitudes of the Sun and (5 naked-eye) planets on a given date. From these we determined the Atlas Charts for the positions of the Sun and planets to find what constellation each was in. We then calculated the elongations and plotted their positions for an observer at sunset and in the solar system.

Planetary Longitude measured eastward

along the ecliptic from  $\gamma$  to  $360^\circ$ .

Elongation = angle from Sun to object.

## 14. Moon Phases

Filled out a table of phases, elongations, rising time, transit time, and setting time for the eight phases from one piece of given information on each.

## 15. Graphic Timetable: Events of a Single Night

After answering questions about the the Sky & Telescope Skygazer's Almanac, we used it to find all the events that will occur during the night of Feb. 22-23, 2026.
